Lab 1: Exploring Datasets

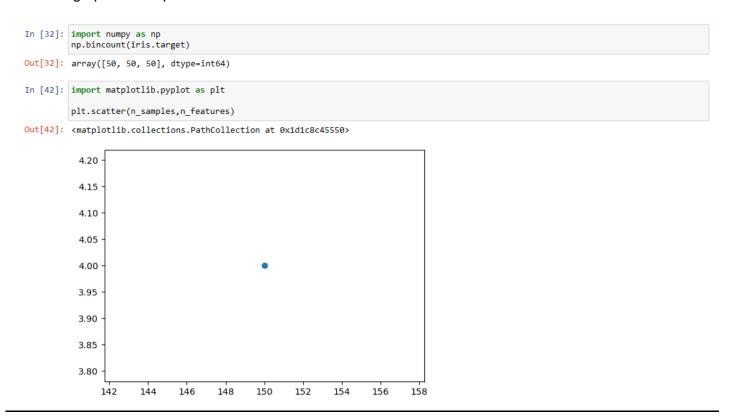

#### **IRIS DATASET:**

- Features in the Iris dataset:
  - 1. sepal length in cm
  - 2. sepal width in cm
  - 3. petal length in cm
  - 4. petal width in cm
- Target classes to predict:
  - 1. Iris Setosa
  - 2. Iris Versicolour
  - 3. Iris Virginica

```

Lab 2: FIND-S ALGORITHM FOR ENJOY SPORT:

**Program 2** – Implement and demonstrate the FIND-S algorithm for finding the most specific hypothesis based on a given set of training data samples. Read the training data from a .CSV file Data set:Enjoysport

a. Enjoysport

Example	Sky	AirTemp	Humidity	Wind	Water	Forecast	EnjoySport
1	Sunny	Warm	Normal	Strong	Warm	Same	Yes
2	Sunny	Warm	High	Strong	Warm	Same	Yes
3	Rainy	Cold	High	Strong	Warm	Change	No
4	Sunny	Warm	High	Strong	Cool	Change	Yes

#### **Algorithm:**

initialize h to the most specific hypothesis in H h- $(\emptyset, \emptyset, \emptyset, \emptyset, \emptyset, \emptyset)$ 

- 1. First training example X1=< Sunny, Warm. Normal, Strong Warm Same>. EnjoySport=+ve Observing. The first training example, it is clear that hypothesis h is too specific. None of the "Ø" constraints in h are satisfied by this example, so each is replaced by the next more general constraint that fits the example h1 = < Sunny, Warm, Normal, Strong Warm, Same>.
- 2.Consider the second training example x2 < Sunny, Warm, High, Strong, Warm, Same>. EnjoySport+ve. The second training example forces the algorithm to further generalize h, this time substituting a "?" in place of any attribute value in h that is not satisfied by the new example. Now h2 =< Sunny, Warm, ?, Strong, Warm, Same>
- 3. Consider the third training example x3< Rainy, Cold, High, Strong, Warm. Change EnjoySport ve. The FIND-S algorithm simply ignores every negative example. So the hypothesis remain as before, so 13=< Sunny, Warm, ?, Strong, Warm, Same>
- 4. Consider the fourth training example x4 <Sunny, Warm, High. Strong. Cool, Change, EnjoySport +ve. The fourth example leads to a further generalization of h as h4=< Sunny, Warm, ?, Strong, ?, ?>
- 5. So the final hypothesis is < Sunny, Warm, ?, Strong, ?, ?>

## Laba: Find s-algorithm.

Implement and demonstrate the finds algorithm for finding the most specific by pothesis land on given set of training data as ocs file.

dataset: Enjoy sport:

Ex Sky Air temp Humidily wind Water forced Evjey
Sport

1 Sunny warm Normal Strong warm same yes
2 Sunny warm Normal Strong warm same yes
3 Rainy Cold Normal Strong warm thange No
4 Sunny warm Normal Strong Cold Chage yes.

# Algorithm of FIND-s:

- 1). Initialize h to most specific hypothesis in H.
- S). For each positive training instance &

  for each vattribute constraint as in h.

  If the constraint as is safisfied in &.

  then do m

elle replace ai in h by the most general constraint that is satisfied by a

3. Output the hypiothesis h.

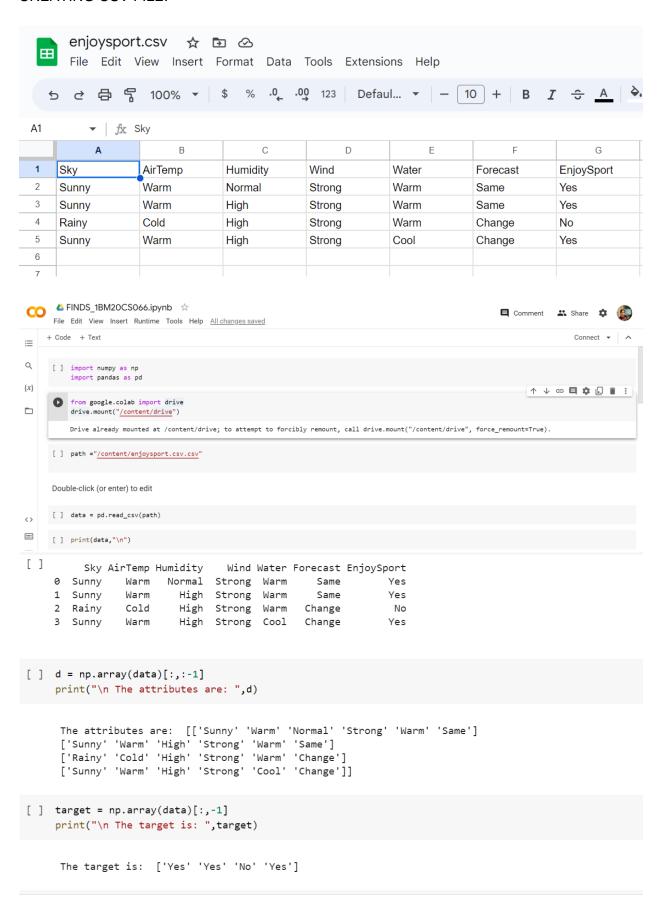

1) h= < p, p, p, p, p, p, p>

, warm

#1 = (Surry, warm, normal, strong, same)
h1 = (Surry, warm, normal, warm, strong, same)

for i, ual in enumerate (c): ûf t[i] == "yes". apaigio for & in range (len (specific hypothesis) if val [x]! = Specific - hypothesis [x]: Specific-hypothesis [x] = '?' else: vielum specific-hypothesis print ("Final hypothesis:", finds (d, target)) SECOND DATASET :import numpy as np. import pand as as pd From google colab import drive. drive mount ("contents/drive") prath = " /content /finds\_IBM20(5066 - Sheels-CSV" FOR CHECKED AND THE CONTROL OF data = pd. sead \_csv (path) print ( data, " \n") d - np. array (data [:, :-1] print i'n vattributes are: ", d) target = np. array (data) [:, -1]

D14	Rain	Mild	High	Strong	No

#### **ALGORITHM:**

- · Create a Root node for the tree
- · If all Examples are positive, Return the single-node tree Root, with label = +
- · If all Examples are negative, Return the single-node tree Root, with label = -
- If Attributes is empty, Return the single-node tree Root, with label = most common value of Target\_attribute in Examples
  - Otherwise Begin
- · A ← the attribute from Attributes that best\* classifies Examples
- · The decision attribute for Root  $\leftarrow$  A
- For each possible value,  $v_i$ , of A,
- Add a new tree branch below *Root*, corresponding to the test  $A = v_i$
- · Let *Examples*  $v_i$ , be the subset of Examples that have value  $v_i$  for A
- · If  $Examples_{vi}$ , is empty
- Then below this new branch add a leaf node with label = most common value of Target\_attribute in Examples
- · Else below this new branch add the subtree ID3( $Examples_{vi}$ , Targe\_tattribute, Attributes {A}))
- · End
- · Return Root

1	x		у
2		1	1
3		2	2
4		3	1.3
5		4	3.75
6		5	2.25
7			

#### **ALGORITHM:**

- The main function to calculate values of coefficients
- Initialize the parameters.
- Predict the value of a dependent variable by giving an independent variable.

dt: 12/05/2023

- Calculate the error in prediction for all data points.
- Calculate partial derivatives w.r.t a0 and a1.
- Calculate the cost for each number and add them.
- Update the values of a0 and a1.

```

#### **Conclusion:**

This model is not appropriate for this model. All the points of this dataset are away from the prediction line.

Program 6:Write a program to implement the naïve Bayesian classifier for a sample training data set stored as a .CSV file. Compute the accuracy of the classifier, considering few test data sets Data set used:

4	Α	В
1	outlook	play
2	rainy	Yes
3	sunny	Yes
4	overcast	Yes
5	overcast	Yes
6	sunny	No
7	rainy	Yes
8	sunny	Yes
9	overcast	Yes
10	rainy	No
11	sunny	No
12	sunny	Yes
13	rainy	No
14	overcast	Yes
15	overcast	Yes

#### Algorithm:

 $P(A \mid B) = \frac{P(B \mid A)P(A)}{P(B)}$ 

Formula for naive bayes classifier is as follows  $\rightarrow$ 

- 1. Convert the given dataset into frequency tables.
- 2. Generate Likelihood table by finding the probabilities of given features.
- 3. Now, use Bayes theorem to calculate the posterior probability.
- 4. Test accuracy of the result and visualizing the test set result.

### **Program 8: KNN ALGORITHM**

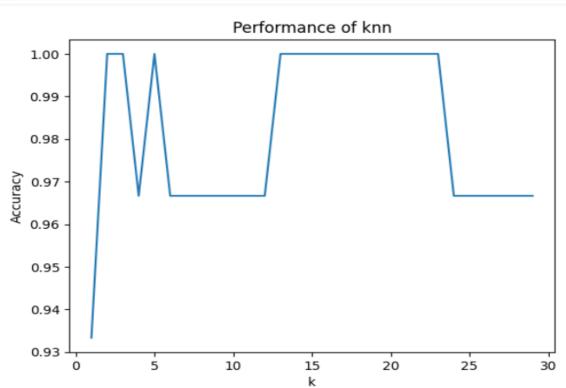

#### Dataset used: Iris dataset

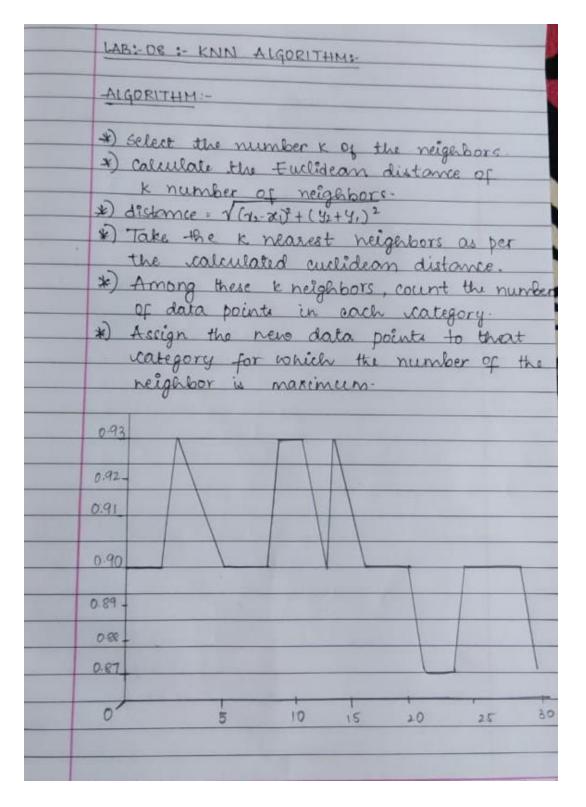

## Algorithm:

- Select the number K of the neighbor
- Calculate the Euclidean distance of K number of neighbors
- Take the K nearest neighbors as per the calculated Euclidean distance.
- Among these k neighbors, count the number of the data points in each category.
- Assign the new data points to that category for which the number of the neighbor is maximum.

```
import numpy as np
import matplotlib.pyplot as plt
from sklearn import datasets
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import StandardScaler
def most common(lst):
    return max(set(lst), key=lst.count)
def euclidean(point, data):
    # Euclidean distance between points a & data
    return np.sqrt(np.sum((point - data)**2, axis=1))
class KNeighborsClassifier:
    def __init__(self, k=5, dist_metric=euclidean):
        self.k = k
        self.dist_metric = dist_metric
    def fit(self, X_train, y_train):

plt.show()
```

**Program 9:** Program: Apply EM algorithm to cluster a set of data stored in a .CSV file. Compare the results of k-Means algorithm and EM algorithm.

Algorithm for k means clustering:

- Initialize k means with random values
- For a given number of iterations:
- Iterate through items:
- Find the mean closest to the item by calculating the euclidean distance of the item with each of the means
- Assign item to mean
- Update mean by shifting it to the average of the items in that clusters

# Algorithm for EM algorithm:

- The very first step is to initialize the parameter values. Further, the system is provided with incomplete observed data with the assumption that data is obtained from a specific model.
- This step is known as Expectation or E-Step, which is used to estimate or guess the values of the missing or incomplete data using the observed data. Further, E-step primarily updates the variables.
- This step is known as Maximization or M-step, where we use complete data obtained from the 2<sup>nd</sup> step to update the parameter values. Further, M-step primarily updates the hypothesis.
- The last step is to check if the values of latent variables are converging or not.

Dataset: Iris dataset

```
import matplotlib.pyplot as plt

**Program 10:**Implement the non-parametric Locally Weighted Regression algorithm in order to fit data points. Select the appropriate data set for your experiment and draw graphs.

#### Algorithm:

1. F is approximated near Xq using a linear function:

$$\hat{f}(x) = w_0 + \sum_{u=1}^k w_u K_u(d(x_u, x))$$

2. Minimize the squared error:

$$E_3(x_q) \equiv \frac{1}{2} \sum_{x \in k \text{ nearest nbrs of } x_q} (f(x) - \hat{f}(x))^2 K(d(x_q, x))$$

$$\Delta w_j = \eta \sum_{x \in k \text{ nearest nbrs of } x_q} K(d(x_q, x)) (f(x) - \hat{f}(x)) a_j(x)$$

It is weighted because the contribution of each training example is weighted by its distance from the query point.

Dataset: tip.csv

```
import matplotlib.pyplot as plt
import pandas as pd
import numpy as np
